🏆 PayShield: The Ultimate Hackathon Cheat Sheet & Pitch

Everything you need to know, present, and win with PayShield.

---

1. The Core Problem 🚨

The Blind Spot in Modern Payments: Online payment fraud costs the global economy **$48 billion annually**. While systems are great at stopping brute-force attacks and SQL injections, they fail at one critical vector: **Client-Side API Tampering**.

Modern web applications trust the browser. When a user clicks "Pay ₹25", the browser sends an API request to the server. But between the browser and the server lies the attacker's playground. Using proxy tools or browser extensions (like Requestly), attackers can silently intercept that request mid-flight and change the amount, the currency, or the destination account.

Why it matters:

- Current Web Application Firewalls (WAFs) only look for malicious code, not altered business logic.
- Traditional fraud engines only score the data *after* it arrives, assuming it hasn't been tampered with.
- The server processes the fraudulent transaction because it looks perfectly legitimate.

---

2. The Solution: PayShield 🛡️

PayShield is an AI-Powered Fraud Intelligence System that closes the gap between the client and the server. It detects API tampering in real-time, scores transactions using Machine Learning, and provides instant visibility through a live dashboard.

How it works (The 3 Pillars of Defense):

1. **Middleware Tamper Detection (The Gatekeeper):** An ultra-fast Node.js middleware sits at the edge of the API gateway. It inspects every incoming request for injected headers or modified signatures characteristic of proxy interceptions. If tampering is detected, it flags the request *before* it even hits business logic.
2. **AI Fraud Scoring (The Brain):** A Python-based XGBoost Machine Learning model evaluates every transaction based on multiple features (amount variance, device fingerprint velocity, geographical distance, card BIN risk). It returns a precise risk score (0.0 to 1.0) in under 50ms.
3. **Real-Time Intelligence (The Eyes):** A Next.js dashboard uses WebSockets and Redis Pub/Sub to visualize the entire payment pipeline live. It features a "Replay Engine" that allows security analysts to step through exactly how a transaction was processed and why it was blocked.

---

3. The Tech Stack 🛠️

A modern, highly-scalable, microservices architecture entirely containerized with Docker.

- **API Gateway:** Node.js, Express, Redis (Rate limiting, Idempotency, Tamper Detection)
- **Fraud Engine:** Python, FastAPI, XGBoost/Scikit-learn (ML Scoring)
- **Dashboard (Frontend):** Next.js, React, Tailwind CSS, Lucide Icons
- **Real-time Layer:** WebSockets (ws), Redis (Pub/Sub)
- **Infrastructure:** Docker & Docker Compose
- **Demo / Attack Simulation:** Requestly Browser Extension

---

4. The Novelty & "Wow" Factor (Why You Win) 💡

The USP (Unique Selling Proposition): Most hackathon projects *talk* about security. PayShield *demonstrates* it live under active attack.

1. **Live Attack Simulation (The Requestly Integration):** We don't just show a static dashboard. We actively attack our own API during the demo using a real-world tool (Requestly) to modify headers mid-flight, proving the system catches exactly what it claims to catch.
2. **The Replay Engine:** It's not just a log file. It's a visual timeline (step 1 to 6) showing exactly what happened inside the server during a transaction. It abstracts complex backend logs into a beautiful, understandable UI.
3. **Microservices Execution:** Building a fully functional 4-container microservice stack (Gateway + Python ML + UI + Redis) that talks to each other in real-time over WebSockets in 24 hours is a massive engineering flex.

---

5. The Winning Pitch 🎤

This pitch is structured to maximize impact, tell a compelling story, and demonstrate technical depth.

Opening Hook (1 Min)

"Imagine you're buying a coffee online for ₹150. You click 'Pay'. Simple, right? But what if, in the 50 milliseconds it takes for that click to reach the server, an attacker intercepted the request and changed the amount to ₹1,50,000 to buy a laptop, routed to their account?

This is called Client-Side API Tampering. It bypasses conventional firewalls because the request looks perfectly legitimate to the server. It's a massive blind spot costing the industry billions.

We built **PayShield** to close that blind spot."

The Solution & Architecture (1 Min)

"PayShield is an AI-driven fraud intelligence system. It operates on three layers: First, a **Node.js Gateway** with custom middleware that detects proxy and extension tampering in real-time. Second, a **Python-based FastAPI Fraud Engine** running an XGBoost ML model that scores risk based on device signatures and geographical data. Third, a **Real-time Next.js Dashboard** powered by Redis Pub/Sub that visualizes the entire threat landscape instantly."

The Live Demo (The "Wow" Moment) (2.5 Mins)

(Switch to Dashboard) "Let's look at the live system. You can see transactions flowing normally. We generate risk scores and everything passes gracefully."

(Point to Requestly or the TEST TAMPER button) "Now, let's attack our own system. We are using **Requestly**, a powerful browser extension that can intercept and modify network requests—exactly what a bad actor might use. I'm going to activate a rule that silently modifies the payment headers mid-flight."

(Click TEST TAMPER) "Boom. Instant block. In less than 2 milliseconds, our Gateway detected the injected header from the tampering attempt. It flagged the transaction, the ML model logged the anomaly, and it was blocked with a 402 Payment Required status. The dashboard alerted us instantly via WebSockets."

(Open Replay Engine) "But blocking isn't enough; analysts need to know *why*. Our **Replay Engine** reconstructs the request. Step 1... Step 2... look right here: 'Tamper Detection: FAILED - Header Present'. We caught the invisible attack."

The Conclusion (30 Secs)

"In 24 hours, we built a secure, scalable, 4-tier microservice architecture that doesn't just block fraud statistically, but actively defends against real-time API manipulation. With PayShield, you don't just hope the request is safe; you prove it. Thank you."
